Data Structures and Fundamentals of Programming

Problem 1
In C++ implement a generic class, called Queue<T>, that uses a single-linked list implementation. This should implement the queue abstract data type (ADT). It should be generic on the type of the data to be stored. Give all class definitions and implement the following for Queue:
- Default constructor
- Destructor
- Copy-constructor
- Assignment operator – using standard copy semantics
- enqueue(T) – takes a parameter of type T and adds it to the queue
- T dequeue() – removes an item from the queue

Your implementation can NOT use STL or any other libraries (standard or otherwise).

Problem 2
In C++, implement a String abstract data type (ADT) using a dynamically allocated array. The array of char should be NULL terminating. This dynamic version of the String will only allocate exactly the amount of memory necessary to store the characters. That is, the length will always be the same as the capacity. However, the size of the dynamic array needs to have an extra char for the NULL terminator.

You must implement the following methods:
- Default constructor that sets the object to the empty string.
- Constructor that takes a const char array and converts it into a string.
- Copy constructor
- Destructor
- Swap – swaps two strings in constant time regardless of the size of the array.
- Assignment operator using standard copy semantics
- Concatenation (String operator+(const String&) const;) that concatenates any two strings and returns a new string with the proper amount of allocated memory.

Your implementation can NOT use STL or any other libraries (standard or otherwise). You cannot use std::string.

Problem 3
In C++ implement a binary search tree abstract data type (ADT) that uses dynamic memory allocation. Make it a tree of integers. Along with the class definition(s), you must implement the following methods for the class:
- Default constructor
- Destructor – must be recursive or use a recursive method to deallocate the tree.
- Copy-constructor – must be recursive or use a recursive method to copy the tree.
- insert which takes a parameter of type integer and creates a new node that is added to the tree in the correct position based on the rules of a binary search tree.

Your implementation can NOT use STL or any other libraries (standard or otherwise).
